Robert Schuman Centre for Advanced Studies

The Robert Schuman Centre for Advanced Studies (RSCAS), created in 1992 and directed by Professor Brigid Laffan, aims to develop inter-disciplinary and comparative research and to promote work on the major issues facing the process of integration and European society.

The Centre is home to a large post-doctoral programme and hosts major research programmes and projects, and a range of working groups and *ad hoc* initiatives. The research agenda is organised around a set of core themes and is continuously evolving, reflecting the changing agenda of European integration and the expanding membership of the European Union.

Details of the research of the Centre can be found on:

<http://www.eui.eu/RSCAS/Research/>

Research publications take the form of Working Papers, Policy Papers, Policy Briefs, Distinguished Lectures, Research Project Reports and Books.

Most of these are also available on the RSCAS website:

<http://www.eui.eu/RSCAS/Publications/>

The EUI and the RSCAS are not responsible for the opinion expressed by the author(s).

The Global Governance Programme at the EUI

The Global Governance Programme is one of the flagship programmes of the Robert Schuman Centre for Advanced Studies at the European University Institute (EUI). It aims to: build a community of outstanding professors and scholars, produce high quality research and, engage with the world of practice through policy dialogue. At the Global Governance Programme, established and early career scholars research, write on and discuss, within and beyond academia, issues of global governance, focussing on four broad and interdisciplinary areas: European, Transnational and Global Governance; Global Economics; Europe in the World; and Cultural Pluralism.

The Programme also aims to contribute to the fostering of present and future generations of policy and decision makers through its unique executive training programme, the Academy of Global Governance, where theory and “real world” experience meet. At the Academy, executives, policy makers, diplomats, officials, private sector professionals and academics, have the opportunity to meet, share views and debate with leading academics, top-level officials, heads of international organisations and senior executives, on topical issues relating to governance.

Abstract

The realization of many of the sustainable development goals (SDGs) depends on bolstering the performance of services sectors and improving access to specific services in developing countries. We show that prevailing services trade and investment policies impact on access to services that matter for the realization of a number of SDGs: lower trade restrictiveness is an instrument that can enhance the performance of domestic services sectors. An implication is that pursuit of the SDGs should include a focus on facilitating trade and investment in services.

Keywords

Services; trade policy; sustainable development goals.

JEL Classification: L8; O10; O24

1 Introduction

The sustainable development goals (SDGs) are a major focal point for international efforts to promote global welfare for the next decade (United Nations, 2015). The SDGs span 17 broad objectives ranging from poverty reduction to improving public health and protecting the environment.¹ International trade and trade policy is one means of implementing the SDGs. A number of goals explicitly reference trade-related measures as instruments that can help to attain the objective concerned. Thus, Goal 2 (ending hunger) includes a call to correct and prevent distortions in world agricultural markets, including through the elimination of all forms of agricultural export subsidies and measures with equivalent effect. Goal 8 (decent work and economic growth) recognizes the role for Aid for Trade support for developing countries, especially for the Least Developed Countries (LDCs). Goal 9 (resilient infrastructure and inclusive industrialization) notes the need for trans-border connectivity and increasing the integration of small-scale industrial and other enterprises into international value chains. Goal 10 (reducing inequality) emphasizes the importance of special and differential treatment for developing countries' trade, in accordance with WTO agreements. Goal 14 (conservation of maritime resources) points to the need to reduce rich countries fishery subsidies.

The main link between the SDGs and trade policy is made in Goal 17 (strengthening the global partnership for sustainable development). This stresses the importance of a universal, rules-based, open, non-discriminatory and equitable multilateral trading system; timely implementation of duty- and quota-free market access on a lasting basis for all LDCs, supported by rules of origin that are transparent, simple and facilitate market access; and respecting national policy space and leadership to establish and implement policies to realize the goals.

The trade policies that are referenced in the text of the SDGs centre on actions that importing countries could (should) take to facilitate market access for exporting firms in developing countries, policy space for developing countries and technical and financial assistance to bolster productive supply capacity and address infrastructure weaknesses. Preferential market access, removing policies that distort global markets and create incentives for excessive exploitation of non-renewable natural resources, and aid to enhance the capacity to use trade for sustainable development can contribute significantly to achieving a number of the SDGs. It is important to note, however, the conceptualization of the role of trade in the wording of the SDGs. Implicitly if not explicitly, the emphasis is on measures to facilitate developing country merchandise exports. Low-income countries may have a revealed comparative advantage in services such as transport, travel and tourism-related activities or business process outsourcing. Moreover, services of all types are becoming easier to trade as a result of technological change, creating opportunities for firms in developing countries to expand trade in nontraditional products, services as well as goods. About one quarter of all LDCs are net exporters of services. For the LDCs as a group, services exports grew more rapidly than for the world as a whole during the 2000s. LDCs increased their share of global trade in services from 0.4 percent in 2005 to 0.8 percent in 2015, with commercial services exports growing by 14 percent over this period, more than twice the rate of other countries, and services exports as a whole represented some 20 percent of total LDC exports of goods and services in 2015 (WTO, 2016).

Services matter for the realization of the SDGs not just because they are a potential source of foreign exchange revenue and associated employment and household income. Services matter also because realization of many of the SDGs is conditional on enhancing the performance of a range of specific services sectors in developing countries. Attaining the SDGs is to a significant extent a services agenda. Eliminating poverty and hunger, improving health and educational outcomes, or reducing regional inequalities will require boosting services capacity and the productivity of a

¹Appendix A lists all of the SDGs.

range of services activities, including transport, distribution, logistics, ICT, vocational training, medical services and so forth.

The goal of this paper is to provide a conceptual framework for considering the role of trade in services in the effort to attain the SDGs. We make a case for devoting greater effort to identify at country-level if and how actions to promote trade in services can support the achievement of some of the SDGs. We focus on two dimensions of the role that services trade policy can play in attainment of the SDGs. The first is the link between service sector performance and economic growth and incomes. Increasing per capita income is critical in realizing many SDGs, both directly – e.g., in the case of reducing the incidence of poverty and hunger – and indirectly, by generating additional domestic resources that can be allocated to measures targeting specific SDGs. Given that services account for a significant share of employment and GDP in all countries, improving service sector productivity is one avenue to increase real incomes (foster economic growth). Greater trade in services, in turn, is a potential instrument to generate higher growth rates.

The second dimension of the role that services trade policy may play in helping to realize SDGs is by bolstering access to specific types of services that are either important “inputs” for some of the SDGs or “outputs” that highly correlate with achieving a specific goal. Many of the SDGs require better access to higher quality services. Others call for improving connectivity-providing service networks.

Whether and how changes to services trade and investment policy can enhance overall economic growth performance (per capita incomes) and access to services that matter for specific SDGs is an empirical question. The analysis in this paper is illustrative. The aim is to discuss the potential role that trade in services can play in the context of achieving the SDGs and to undertake an initial empirical assessment of the salience of the alternative channels through which trade policies towards services can impact of the SDGs. The feasibility of rigorous cross-country quantitative study of the channels through which services trade and services trade policies may impact on SDGs is limited by data constraints. The absence of comparable time series information on services trade policies severely impedes empirical analysis that can appropriately consider endogeneity and identification issues. We are therefore limited to an exploratory investigation that uses available data on services trade policy to assess to what extent such policies are associated with outcomes that matter from an SDG perspective.

The findings suggest that services trade and investment policy may matter more for enhancing access to services than for increasing overall economic growth, although we find that more liberal trade policies towards transport services are positively associated with per capita income levels. Services trade policies appear to have a stronger association with measures of the availability of (access to) a number of services that figure prominently in the text of several SDGs: financial, ICT and transport services. We also find that the relationship between services trade policy regimes and access to (performance of) services sectors is influenced by the quality of prevailing regulatory institutions. A policy implication of the analysis is that more attention should be given to trade policies for services and related regulatory and economic governance institutions in the international effort to attain the SDGs. Which types of services matter more for different SDGs requires country-specific analysis, which is likely to be less affected by the data limitations that constrain cross-country analysis of the impact of services trade policy on SDGs. We hope that our findings will motivate such research and more generally stimulate greater consideration of services trade policies in country-level efforts to identify and implement measures that will help attain the SDGs.

2 Services and the SDGs

The performance of services sectors in an economy may impact on the prospects of attaining the SDGs through two main channels. The first is indirect: through the impact on per capita income, as more efficient and productive services sectors can increase economic growth which in turn is important for the overall achievement of the SDGs. The second channel is direct: improving access to, and the quality of, specific types of services is central to a number of the SDGs.

2.1 Services and economic development

One of the stylized facts of economic development is that the share of services in GDP and employment rises as per capita income increases.² In the lowest-income countries, services generate some 35-40 percent of GDP. This rises to over 75 percent of national income and employment in many OECD countries. An increasing share of services in GDP and employment is part and parcel of economic development. The expansion in the services-intensity of economies as they become wealthier is driven by a number of factors.³ Standard explanations involve both demand and supply side factors. Growth in the share of services as countries grow richer is in part a function of changes in final demand patterns and higher average income elasticities of demand for services than for goods. It also reflects differential labor productivity growth across sectors, technological changes that support greater specialization by firms through outsourcing of services tasks, and associated growth in demand for coordination and intermediation services (Schettkat and Yocarini, 2006; Francois and Hoekman, 2010; De Backer et al., 2015).

While an expanding share of services in total output and employment for the world as a whole is nothing new (see for example Kravis et al., 1983), for any level of economic development or per capita income, the role of services in the economy is today more important than in the past as a result of advances in information and communication technologies and transport. Growth in the share of services in GDP is part of the process of structural transformation that is associated with rising per capita income levels. In part it reflects the inter-sectoral reallocation of factors of production from low-productivity agriculture and informal services to higher-productivity activities in the formal sector (industry and services). Just as salient are shifts within sectors, including increasing demand for intermediate services (Berlingieri, 2015). Resource allocation shifts within services sectors are a driver of productivity growth in the same way as in goods-producing sectors (Young, 2014).

Efficient services are critical for economic development because they are determinants of the productivity of capital and labour. Financial services intermediaries are critical in providing funds to firms that have been generated by households seeking to invest their savings. Health and education services are key ‘inputs’ that help determine the skills and quality of life of workers. Other services are the backbone of connectivity, ‘facilitating’ the physical movement of goods and people (transport services) and the exchange of knowledge and information (communications services).⁴ Telecommunications are crucial to the dissemination and diffusion of knowledge including through the Internet. ICT services are a transport mechanism for information services and other products that can be digitized. Similarly, transport services affect the cost of shipping goods and movement of workers within and between countries. Business services such as accounting, engineering, consulting and legal services reduce transaction costs associated with the operation of financial markets and the enforcement of contracts, and are a channel through which

²Buera and Kaboski (2009) suggest that the relationship between the share of services in GDP and log per capita income is linear.

³See, e.g., Baumol (1967), Fuchs (1968).

⁴OECD/WTO (2017) offers an excellent discussion of the role of services and services trade for connectivity.

process innovations are transmitted across firms in an industry and across industries. Health and education services are key inputs into and determinants of the stock and growth of human capital. In short, the performance of the services sector matters for economic growth and the overall productivity of the economy as a whole. From an SDG perspective this implies that a first channel through which services performance matters is through the income channel.

2.2 Services and the SDGs

The indirect link between services and economic development that operates through the effect of service sector performance on economy-wide productivity and real income growth is just one channel through which services are relevant to the SDGs. While it is an important channel, as, for example, per capita income growth will help achieve the poverty reduction SDG, service sector performance is very salient for many “non-income” dimensions of the SDGs and their associated specific targets.⁵ Some SDGs directly depend on the performance of specific services sectors (e.g., health services in SDG 3 and education services in SDG 4). Eleven of the 17 SDGs explicitly refer to (or implicate) at least one distinct service sector as a means of attaining the goal in question. This generally spans one or more of the following elements:

Access to services: expanding access or improving the affordability of a given services activity, output or product;

Quality of services: enhancing the quality, efficiency, capacity or resilience of a service sector; and

Environmental services: reducing the environmental footprint (negative spillover effects) of an economic activity.

Table 1 illustrates some of the linkages between services and SDGs. It reports the services sectors that various SDGs refer to, based on a text search of the keywords embodied in the description of the SDGs and the focal point for action implied by (needed to attain) the respective goals.

This text-based mapping exercise illustrates that the intersection between the SDGs and the performance of services sectors is substantial. Services matter for attaining specific SDGs. Beyond access to basic services in the areas of health, education, sanitation, water and energy, access to financial services is identified in five SDGs (the most frequent reference across services sub-sectors). Other services that are mentioned include ICT services, improved quality, efficiency, capacity and resilience of R&D services, tourism, transport, construction and waste management services. SDGs that aim at reducing the negative environmental footprint of economic activity also identify specific services sectors, including sanitation, water and energy related distribution services, transport, construction, and waste management services.

The fact that services are not explicitly referenced in a SDG and for that reason are not listed in Table 1 does not mean, of course, that services do not matter for such goals. In the case of SDG 5 (gender equality), for example, and the SDGs addressing environmental sustainability (13, 14 and 15) services can be very relevant. Ngai and Petrongolo (Forthcoming) document the evolution of what they call the comparative advantage of women in the services sector. Services involve safer, cleaner working conditions as well as potentially shorter and more flexible working hours than jobs in factories (Goldin, 2006).⁶ Services are in general not very energy intensive, with the notable exception of transport. This makes services activities relevant for the sustainability of

⁵See Annex 1 for a list of the 17 main SDGs and <https://sustainabledevelopment.un.org/topics/sustainabledevelopmentgoals> for the more detailed targets for each SDG. In what follows we consider both the SDGs and the more detailed targets that are associated with the respective SDGs insofar as they involve specific services activities.

Construction Services	9	Infrastructure	Q and EF
Waste management services	11	Waste management	Q
	12	Recycling / Reuse	Q and EF

Notes: Focal points comprise access (A), quality (Q) and environmental footprint (EF).

development strategies - an increase in the services share or services-intensity of economic activity may be associated with a smaller carbon footprint. Services can also contribute to improving environmental sustainability as inputs into the design of less carbon-intensive production: the basic research, engineering and R&D that is required to identify more sustainable production techniques constitute services activities.⁷ Other services sectors such as finance and insurance are also key ‘facilitators’: helping to mobilize and channel the resources needed to fund investments needed to reduce environmental footprints across economic sectors more generally.

3 Services trade policy and the SDGs

Given the presumption that services performance matters for the attainment of many SDGs, the policy challenge is to encourage improvement in service sector performance. This is a multi-faceted question that in practice will be inherently sector-specific. National specialist agencies responsible for the operation and regulation of health, education, transport, finance, etc. services sectors will need to undertake diagnostic analysis and identify binding constraints and priorities for action. This sector-level engagement constitutes a major dimension of the activities of governments and the support that is provided by development agencies (e.g., Joshi et al., 2015; Ssozi and Amlani, 2015; Koehler et al., 2015; Abbott et al., 2017). Our focus in what follows is on the supportive role services trade and investment policy can play in complementing sector-specific interventions and policy reforms to improve the productivity performance of services sectors and enhancing access to services.

Historically many services were characterized as non-tradable, reflecting their non-storable and

⁷See, for example, Dihel (2010) for a detailed discussion of environmental services and trade in environmental services.

intangible nature. An implication was that international trade in services often required the cross-border movement of providers or consumers, in turn involving the movement of capital and labour. The need for such factor movement has been declining as technical change has allowed services to be digitized and exchanged cross-border through ICT networks and air transportation and information services that facilitate identification of market opportunities. Information and telecommunications advance have increased direct exports of services by allowing the sale/provision of services over ICT networks, and suppliers/customers to physically move to satisfy the proximity constraint that frequently still impede cross-border services transactions. While developments in areas such as software and apps, business process outsourcing, and the like attract much attention, these activities are all dependent on a variety of services inputs that determine the ability of entrepreneurs to participate in international value chains or to sell products directly to clients through B2B or B2C e-commerce platforms. The quality, price and availability of such inputs is determined in part by a country's services trade and investment policies.

Trade costs for services remain much higher than trade costs for goods, and the rate of decline in such costs has been much less than for goods (Miroudot and Shepherd, 2016). The result is to reduce the volume of trade in services by compromising the ability of firms to exploit their competitive advantages on world markets. High services trade costs imply that many services tend to be traded indirectly. Recent initiatives such as the OECD and WTO project to measure trade in value added (TiVA) have illustrated that services account for a significant share of the value added of all sectors in the economy. As this value added is embedded in traded goods, services play a much larger role in international exchange than is measured by a nation's balance of payments (BOP). At least 50 per cent of global trade on a value added basis comprises services: the sum of the value of services output that is traded directly and is captured in BOP statistics (some 20 to 25 per cent of total exports), plus the value of services that is embedded in traded goods (another 25 to 35 per cent). Some of these embedded services are provided by foreign-owned firms. Often the most efficient way for foreign firms to provide services in a market is to establish a commercial presence, i.e., to engage in foreign direct investment (FDI).⁸

There is substantial empirical evidence that services FDI has positive effects on productivity by inducing greater competition and providing access to higher-quality, more varied, and cheaper services (Francois and Hoekman, 2010). Many studies and reports have analysed the role of services trade and related policies from an economic development perspective (see for instance Mattoo and Payton, 2007; Cali et al., 2008; World Bank, 2010; Saez et al., 2015; Dihel and Goswami, 2016; Balchin et al., 2016), complementing research on developed economies (e.g. Breinlich and Criscuolo, 2011; Wagner, 2012). This literature demonstrates that firm heterogeneity plays an important role in shaping patterns of services trade, much as is the case for trade in goods. A robust finding is that an important determinant of service sector performance and thus economy-wide productivity is the role that many services play as inputs into production of both goods and other services.

In the remainder of this paper we explore empirically whether services trade policy can be a tool to support achievement of the SDGs. Consistent with the foregoing discussion, we start with assessing the relationship between services trade policy regimes and economic development (per capita income growth) using a cross-section regression framework. We then go on to investigate the empirical relationship between services trade policy and access to a subset of the services that are highlighted in the various SDGs. In particular, we look at access to financial, ICT and transport services. These three services are frequently referenced in the text of the SDGs and

⁸The importance of FDI as a "mode of supply" implies that the adjustment costs of trade in services may differ from those when trade comprises goods. Because the services are produced locally, greater foreign competition through FDI will generally involve less reallocation of employment across sectors than in the case of liberalization of trade in goods (Konan and Maskus, 2006).

associated targets (Table 1).

3.1 Services trade policy and per capita income growth

We construct a cross-section growth regression framework to estimate the linkages between services trade policy and economic growth. The main database used in this exercise is the World Bank's Services Trade Restrictiveness Database (STRD), which covers 103 countries and provides information on services trade policy for many services sectors including finance, telecommunications, transport and professional services. The indexes in the STRD capture the trade policy regime prevailing in a country in the late 2000s.⁹

The dependent variable is the average growth rate of per capita GDP (PPP) for the 6 year period between 2008 and 2013. We use a standard growth empirical model with the initial level of economic development, education and investment share of GDP plus a number of additional variables in the spirit of Mattoo et al. (2006). In particular we control for the degree of political stability, the level of government consumption, the share of tropical land within the country territory,¹⁰ and Sub Saharan Africa (SSA) and Latin America (LAC) regional dummy variables. We also add a dummy control variable taking the value of one if the country has experienced a systemic financial crisis as measured by the Laeven-Valencia Systemic Banking Crisis Database in the 2007-2011 period.¹¹

The estimation sample contains 92 countries spanning all income categories and geographical regions. Countries are listed in Table B-1 while Table B-2 contains summary statistics, definitions and sources for all the variables used in the estimation. Results are presented in Table 2. In the first five columns the services trade restrictiveness indices (STRIs) are introduced one at a time, starting with the STRI that aggregates trade policy information across the four services sectors used for the analysis. The last column includes all of the sector-specific STRIs jointly.

The estimated coefficients for the initial level of economic development, education and investment share of GDP have the expected signs and are statistically significant across all the specifications in Table 2.¹² All the other growth controls have the expected signs, with the exception of share of tropical land and the Latin America dummy. However, neither of these is statistically significant.

Turning to the services trade policy coefficient estimates, the overall STRI does not appear to have any effect on growth performance. The same is true when sector-specific STRIs are included separately: coefficients are never statistically significant. Only for the case of transport services is the sign of the coefficient estimate suggestive that less restrictive trade policy regimes are associated with higher economic growth (column 4). However, the estimate is not statistically different from zero. These patterns remain robust when we include all the sector-specific STRIs in the growth equation (column 6), with the exception of the coefficient for the STRI for transport, which becomes statistically significant and doubles in magnitude. The estimate implies that reducing restrictions to trade in transport services by the equivalent of half of one standard deviation is associated with an 0.25 percentage point increase in the average growth rate. Analogous results are obtained if we replicate the estimation using only data for STRIs

⁹For a detailed description of the STRD see Borchert et al. (2014).

¹⁰We are grateful to Ulrich Sperling for providing the climate data. In particular, the shares of tropical land within the country territory were computed by the Geographical Institute of the University of Bern using the Köppen-Geiger climate classification data.

¹¹The findings presented below are stable if only data for the 2010-2013 period is used so as to reduce the potential effects of the global financial crisis. Furthermore, results remain qualitatively robust when restricting the estimation sample to non high income countries. Regression results are available upon request.

¹²The initial level of economic development, education and investment share of GDP are those determinants of growth identified as empirically robust by Levine and Renelt (1992).

services trade policies are not particularly salient. However, this is not necessarily the case. One explanation for the finding that, apart from the transport sector, services trade policy does not appear to be a determinant of the cross-country variation in average economic growth is that STRIs by themselves may not fully capture the policy factors that constrain services trade and investment. In practice a variety of product market regulation measures and the quality of a country's investment climate and economic governance may have a greater impact on services trade and investment than the discriminatory policies that make up the STRIs. Recent research concludes that the effect of STRIs may be conditional on the incidence of other policies that affect the business environment, in particular the quality of domestic institutions and economic governance (see for instance van der Marel, 2012; Beverelli et al., 2017).

3.2 Services trade policy and access to services

In this section we investigate the effects of STRIs on indicators of access to services that are relevant to various SDGs. In particular, we focus on access to financial, ICT and transport services, three sectors for which there are STRI data and that appear frequently in the texts of the different SDGs. We use a simple bivariate regression model to estimate the conditional expectation function of a services related SDG-outcome given the prevailing services trade policy regime for the respective services sector. As discussed previously, the presumption is that less restrictive trade policies should be associated with better services performance (access to or

availability of services) which in turn supports the realization of the relevant SDGs.¹⁴ We take into account particular features of the economic environment that are likely to affect the relationship between access to services that matter for SDG outcomes and services trade policy.

The following sector-specific interaction model is estimated:

$$SDG\text{-outcome}_i = \alpha + \beta STRI_i + \gamma Moderator_i + \delta(STRI_i \times Moderator_i) + \epsilon_i \quad (1)$$

Two moderator variables are used. The first is the level of economic development (GDP per

¹⁴See for example D'Amelio et al. (2016).

capita). For many SDGs, increasing per capita income is important for the achievement of the goal, suggesting a need to test whether the relationship between services trade policy and services access-related performance indicators are moderated by the initial level of income. We expect a stronger relationship between STRIs and realization of SDG performance indicators when the process of achieving the latter is less constrained by income levels. The second moderator variable is the quality of economic institutions in a country. This second exercise is in the spirit of Beverelli et al. (2017), where economic governance is identified as a key shaping factor for the effect of services trade restrictiveness on productivity of downstream manufacturing industries, controlling for the intensity of use of services inputs into production. The focus here is on access to services as a function of services trade policy which will be affected by the same type of institutional interdependence relationships that have been found to be important by Beverelli et al. (2017).

The non-storability and intangibility of most services gives rise to a proximity burden (Francois and Hoekman, 2010): the agent providing a service must be in the same location as the buyer or consumer. As a consequence, exporters of services often must perform some stages of their economic activity in the importing country, and thus will be affected by local regulations and the prevailing business environment, i.e., the quality of economic governance and related institutions. Accordingly, better institutions should attract more productive services providers and support higher levels of services performance. Therefore, we expect a stronger positive relationship between services trade openness and access to services in countries with higher quality regulatory institutions.

Data on access to financial services is obtained from the Global Financial Development Database (GFDD) of the World Bank. As a proxy for access we take the share of population that is at least 15 years of age and has an account at a formal financial institution.¹⁵ In the case of access to ICT services we consider the number individuals per 100 people who have used the internet in the last 12 months (from any location and via any device). These data are collected by the International Telecommunication Union and is reported in the World Bank's Millennium Development Goals (MDG) Database. Finally, we measure access to transport services using the World Bank Logistics Performance Index. The index reflects perceptions of professionals (freight forwarders) of a country's logistics situation, based on efficiency of customs clearance process, the quality of trade and transport-related infrastructure, ease of arranging competitively priced shipments, the quality of services (ability to track and trace consignments; frequency with which shipments reach the consignee within the scheduled time). The index ranges from 1 to 5, with a higher score representing better performance.

Information on services trade policy is again taken from the STRD described in section 3.1. For each access variable introduced above we use the corresponding sector-specific STRI. We take the overall-modes STRI which, for the case of communication services corresponds to the mode 3 STRI. As the STRI data are for policies prevailing in the late 2000s, for each access variable we use the average of the available values for the 2010-2012 period.¹⁶ Merging the services access and quality indicators and the trade policy data by sector, we end up with three cross-section datasets where the number of countries (observations) is determined by the intersection of the country coverage of the source databases.

Finally, we use data on institutional regimes from the Worldwide Governance Indicators (WGI) database. We use the WGI measure of regulatory quality as a proxy for the prevailing insti-

¹⁵The results reported below are robust to using other measures of consumers' access to basic financial services. The results also hold for proxies for firms' access to financial services, which is an important determinant of firms' performance (see Chauvet and Jacolin, 2017).

¹⁶Detailed information on the years covered for each variable are given in Table B-3. The results reported below are robust to modifications of the average time period, in particular taking into account the years 2008, 2009 and 2013 when these are available.

tutional framework.¹⁷ The dependent variable is constructed as an averages for the three year period from 2010 to 2012. Table B-3 presents summary statistics by sector.

Table 6 reports the estimation results. The negative signs of the estimated coefficients in the bivariate models (columns 1, 4 and 7) indicate that - ceteris paribus - a lower level of trade restrictiveness for a sector is associated with better access to the services concerned or, in other words, with a higher level of performance in helping to attain the respective SDGs. This relationship is statistically significant for all three services sectors, with levels of significance ranging from the 1% (ICT) to the 10% (transport) level of statistical significance. These results are consistent with the hypothesized positive role of international trade in improving access to services.

Turning to the interaction models, the coefficient estimates for the direct effects of GDP per capita and regulatory quality are positive and strongly significant, meaning that higher levels of economic development and better quality of institutions are positively associated with services access indicators. More interestingly, the coefficient for the interaction term is always negative. When statistically significant, this reflects a moderating role - of either economic development (per capita income) or quality of institutions - in shaping the relationship between services trade policy and measures of access to services that are relevant for the SDGs. In particular, the negative sign implies that the positive association between trade openness and services performance (an input into SDG progress) is stronger for higher values of the moderator variable. The interaction term between GDP per capita and the sectoral STRI is statistically different from 0 for all three sectors, while the interaction between STRI and the quality of domestic institutions is significant for finance and for transport.¹⁸

To get a sense of the behaviour of the STRI-services access relationship as a function of the moderator variable we calculate the estimated partial derivative of equation (1) with respect to STRI, which is given by $\widehat{\beta} + \widehat{\delta} \times \text{Moderator}$. Consider for example the link between financial services trade restrictiveness and access to financial services.¹⁹ Figures 1 and 2 plot this relationship at two different levels of per capita GDP and institutional quality, respectively.²⁰ The solid line in both figures represents the fitted linear relationship when the level of economic development

¹⁷Our results are robust to using other indicators such as the rule of law, control of corruption and political stability.

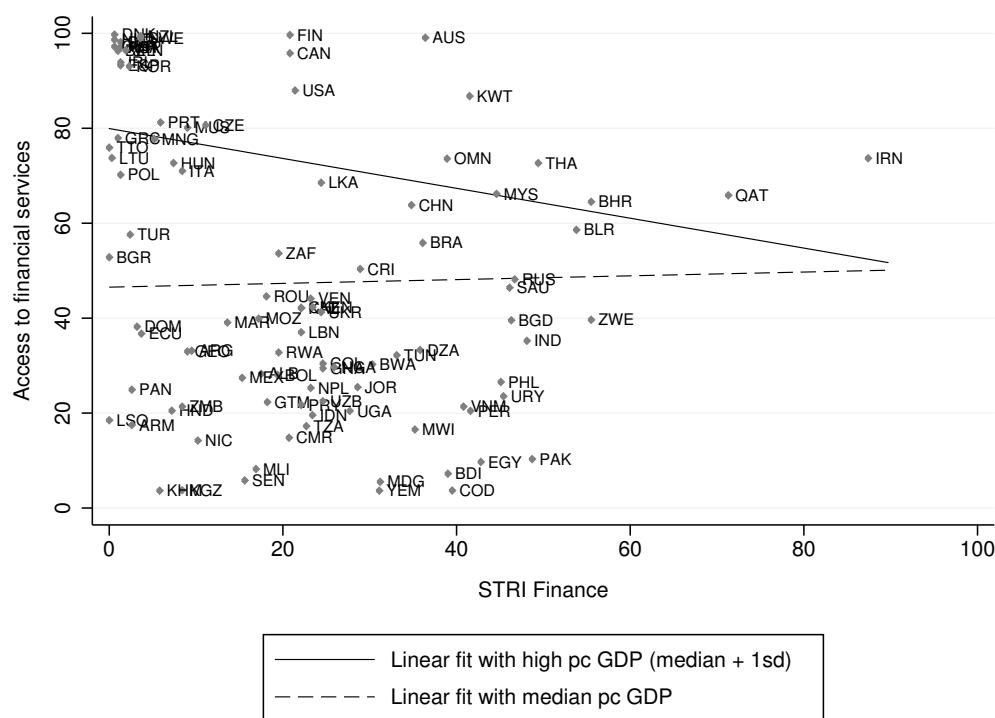

¹⁸The moderating role of institutions suggested by our estimates is consistent with the literature on the complementarities between trade (policy) and institutions (see for instance Rodriguez and Rodrik, 2014; Freund and Bolaky, 2008; Ahsan, 2013; Beverelli et al., 2017).

¹⁹The same patterns emerge for ICT and transport but are reported for space considerations.

²⁰The regression lines in Figure 1 (Figure 2) are obtained fitting the interaction model for per capita GDP and the institutional variable, respectively. We use the estimation from column 2 (column 3) of Table 6, respectively.

(quality of institutions) is at its median value plus one standard deviation. In that case, lower services trade restrictiveness is associated with better access indicators. More precisely, when per capita GDP (quality of institutions) is used as the moderator, a reduction in the sectoral STRI of one half of a standard deviation is associated with an increase in access of 2.8 (3.6) units.²¹ In contrast, when the level of per capita GDP or the quality of institutions are at their median levels, such a positive relationship between lower services trade restrictiveness and better access might not obtain. Indeed, the estimated slope of the dashed line in both figures is not statistically different from 0.²²

Figure 1: Access to financial services and STRI Finance: the role of initial conditions

²¹The estimated slope coefficient and its robust standard error for the solid line are -0.315 and 0.086 in Figure 1; -0.4 and 0.159 in Figure 2.

²²The estimated slope coefficient and its robust standard error for the dashed line are 0.04 and 0.105 in Figure 1; in Figure 2 the respective numbers are 0.081 and 0.130.

Figure 2: Access to financial services and STRI Finance: the role of institutions

4 Conclusion

The realization of many of the SDGs depends in part on bolstering the performance of services sectors and improving access to specific services in developing countries. Conceptually services trade policy can contribute to the SDGs by helping to increase productivity performance of services sectors and thus impact on economic growth, which is an important necessary condition for realising many of the SDGs. Services trade policy can also affect the availability and quality of a variety of services that will determine the attainment of specific SDGs. We have shown that prevailing services trade and investment policies are associated with indicators of access to services that matter for the realization of a number of SDGs, while our data suggests that, with the exception of transport related trade policies, their association with per capita income growth is weak. The available data suggests that reducing levels of services trade and investment restrictiveness is primarily a potential instrument to enhance the access to services sectors that are important to the SDGs. An implication is that policy research should focus on the direct channels between services trade policy and services performance as opposed to the indirect channels between trade openness and growth.

Undoubtedly other policies will be more important in affecting the performance of services, most obviously sector-specific policies and sector-specific regulatory regimes. These appropriately are the focus of SDG-related analysis and projects around the developing world. On the trade front the focus of attention is on measures to facilitate trade in goods with developing countries and to enhance productive capacity. This is also appropriate and important. The aim of this paper is not to argue the contrary. Instead the goal is simply to highlight that trade policies towards services can make a contribution and that analysis of the potential role services trade policies can make should be part of country-level diagnostics and prioritization efforts. Most discussion on the scope to leverage the potential of trade to support achievement of the SDGs is restricted

to merchandise trade. This is exemplified in the Agenda 2030 document that incorporates the SDGs, which highlights measures to increase merchandise exports from developing countries (through duty-free, quota-free access, liberal rules of origin, and giving countries space to pursue industrial policies (United Nations, 2015)). The main policy implication of this paper is that the focus on trade policies should span services trade and investment regimes and not just (or primarily) merchandise trade.

Reducing services trade costs is a neglected dimension of the challenge of realizing the SDGs. Lowering services trade costs will involve not just reducing formal (explicit) barriers to trade (as captured in the STRIs). It is important to recognize that the STRIs that were used for the empirical analysis are just one element of the set of policies that impact on the level of competition on services markets and thus prices and availability of services. When it comes to services trade the quality of economic governance institutions is likely to be particularly important, given that FDI is a major vehicle for foreign suppliers to provide services. Attention must also focus on improving regulatory regimes and on actions to lower the costs for firms in demonstrating compliance with applicable regulatory policies, i.e., on services trade facilitation.

Clearly identification of trade policy-related priorities from the perspective of specific SDGs requires country-level analysis and detailed investigation of the services performance measures that are most salient to a given country context. In this respect the results reported in this paper are intended to be illustrative – suggesting that such analysis is worth undertaking as part of the broader effort to pursue the SDGs.

Appendices

A List of the Sustainable Development Goals

- Goal 1** End poverty in all its forms everywhere
- Goal 2** End hunger, achieve food security and improved nutrition and promote sustainable agriculture
- Goal 3** Ensure healthy lives and promote well-being for all at all ages
- Goal 4** Ensure inclusive and equitable quality education and promote lifelong learning opportunities for all
- Goal 5** Achieve gender equality and empower all women and girls
- Goal 6** Ensure availability and sustainable management of water and sanitation for all
- Goal 7** Ensure access to affordable, reliable, sustainable and modern energy for all
- Goal 8** Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all
- Goal 9** Build resilient infrastructure, promote inclusive and sustainable industrialization and foster innovation
- Goal 10** Reduce inequality within and among countries
- Goal 11** Make cities and human settlements inclusive, safe, resilient and sustainable
- Goal 12** Ensure sustainable consumption and production patterns
- Goal 13** Take urgent action to combat climate change and its impacts
- Goal 14** Conserve and sustainably use the oceans, seas and marine resources for sustainable development
- Goal 15** Protect, restore and promote sustainable use of terrestrial ecosystems, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss
- Goal 16** Promote peaceful and inclusive societies for sustainable development, provide access to justice for all and build effective, accountable and inclusive institutions at all levels
- Goal 17** Strengthen the means of implementation and revitalize the global partnership for sustainable development
