Can Regulation Improve Service Quality?
Evidence from European Air Passenger Rights

Hinnerk Gnutzmann and Piotr Śpiewanowski

Robert Schuman Centre for Advanced Studies

The Robert Schuman Centre for Advanced Studies, created in 1992 and currently directed by Professor Brigid Laffan, aims to develop inter-disciplinary and comparative research on the major issues facing the process of European integration, European societies and Europe's place in 21st century global politics.

The Centre is home to a large post-doctoral programme and hosts major research programmes, projects and data sets, in addition to a range of working groups and ad hoc initiatives. The research agenda is organised around a set of core themes and is continuously evolving, reflecting the changing agenda of European integration, the expanding membership of the European Union, developments in Europe's neighbourhood and the wider world.

Florence School of Regulation

The Florence School of Regulation (FSR) is a partnership between the Robert Schuman Centre for Advanced Studies (RSCAS) at the European University Institute (EUI), the Council of the European Energy Regulators (CEER) and the Independent Regulators Group (IRG). Moreover, as part of the EUI, the FSR works closely with the European Commission.

The objectives of the FSR are to promote informed discussions on key policy issues, through workshops and seminars, to provide state-of-the-art training for practitioners (from European Commission, National Regulators and private companies), to produce analytical and empirical researches about regulated sectors, to network, and to exchange documents and ideas.

At present, its scope is focused on the regulation of Energy (electricity and gas markets), Communications & Media, and Transport.

This series of working papers aims at disseminating the work of scholars and practitioners on current regulatory issues.

Abstract

Under EU Air Passenger Rights legislation ("EC261"), carriers must provide assistance and cash compensation to passengers in case of long delay. We study whether the regulation reduces flight delay. EC261 applies uniformly to flights departing from the EU, but covers only EU carriers on EU–bound flights. Exploiting this variation, we find that regulated flights are 5% more likely to arrive on time, and mean arrival delay is reduced by almost four minutes. The effect is strongest on routes with little competition, and for legacy carriers. Thus, consumer rights can improve quality when incentives from competition are weak.

Keywords

Introduction[*]

Flight delay is a persistent quality problem in the airline industry, which has not been resolved by competition (Ater and Orlov, 2015). Soft-touch regulations, such as the US delay disclosure program, appear to have encouraged gaming (Forbes et al., 2015) rather than service improvement. At the same time, while three-quarters of delay minutes are caused by airline operations or late arriving aircraft, passengers are often left to bear the burden when a delay occurs – be it in terms of inconvenience, lost time or incremental expenses.[1] This paper studies the pioneering EU Air Passenger rights regulation ("EC261"), which makes airlines liable for providing assistance and compensation to passengers in case of long delay. Our main objective is to identify to what extent this liability encourages airlines to improve punctuality.

This paper provides robust evidence that the European air passenger rights regulation (EC261) is effective in reducing average flight delay. Our main estimate reveals an average treatment effect of the regulation of nearly 5 minutes of departure delay reduction. This impact is clearly economically important in magnitude compared to a population average delay of around 12 minutes,[2] and is independent of airlines' decisions on scheduled flight duration. Statistically, the hypothesis of no impact can be very firmly rejected. The results hold for other measures of flight punctuality (arrival delay and share of "on-time flights"), and is robust to alternative specifications. Moreover, we find that the regulation is most effective at delay reduction on routes where competition is low.

Our identification strategy exploits within–route variation in regulatory coverage based on the country of origin of the carrier. This arises from the partial extra–territorial application of the European passenger rights regulation on extra-EU routes (i.e. routes connecting an airport in the EU with an airport outside of the EU). All flights departing from an airport inside the EU are covered. On routes originating outside, only flights operated by EU carriers fall under the regulation; here, we observe flights that are covered and not covered operating on the same route and scheduled around the same time. This makes it possible to identify the impact of the regulation while allowing for carrier fixed effects *and* controlling for route-time effects (e.g. caused by airspace congestion).

These findings have four important implications for the literature. First, EC261 is an example of a policy successful in reducing airline delay; prior research on US regulations generally found them to ineffective in addressing delay. Forbes et al. (2015) study how airlines respond to incentives to "game" the US Department of Transportation (DOT) on-time market transparency program. Under the program, a flight is classified as on-time if delay is less than 15 minutes; this creates particularly strong incentives to reduce reported delay when a flight is expected to have a delay just above this threshold.[3] In a follow-up paper, Forbes et al. (2018) observe impact of the transparency program on *average* delay reduction, which however is a result of increased scheduled duration, not an improvement from flight operations. Relatedly, Fukui and Nagata (2014) study the DOT's tarmac delay rule, which penalizes airlines holding

[1]   See Ball et al. (2010)

[2]   This is true in both the US and Europe. See Eurocontrol (2007) and Bureau of Transportation Statistics' on-time performance database.

[3]   Forbes et al. (2015) find that airlines which self-report their delay time misreport arrival times for flights arriving just after the 15 minute threshold. Second, some airlines operate employee bonus programs that reward performance according to the DOT ranking; these have similar threshold effects even with automatic reporting. This suggests that flights at risk of missing the 15 minute mark may be marginally accelerated. These findings show that the DOT program is subject to gaming at threshold.

passengers on the tarmac for more than three hours with considerable fines (up to $27,500 per passenger). They likewise find evidence consistent with gaming: flights at risk of long tarmac delay may be canceled, and the introduction of the rule may have caused longer gate departure delay.

Secondly, our results provide some empirical evidence on possible positive effects of consumer protection law. As highlighted in the literature on behavioral industrial organization (surveyed in Heidhues and Kőszegi (2018)), consumers may not fully take into account contingencies that are unlikely ex ante when making a purchase decision; for example, they may fail to realize the costs they could face in case of a long flight delay. In this case, making insurance mandatory can protect consumers. As our results show, such a regulation can have broader benefits by encouraging firms to increase average quality. At the same time, the trade-off for these benefits is a reduced freedom of contracts.

Third, our results provide further evidence of low marginal costs of airline delay reduction. The provisions of EC261 apply to flight delays exceeding three hours, which occur on around 0.5% of flights; hence, expected costs of the regulation for any given flight must be low. At the same time, we find large average effects of delay reduction. These results are consistent with Nicolae et al. (2016), who consider the delay reduction impact of introducing checked baggage fees. Charging for baggage may reduce the number of baggage items passengers carry, reducing utilization of ground services and making plane loading faster (they refer to this as the "below-the-cabin effect"). Nicolae et al. (2016) find that carriers introducing baggage fees saw a median reduction in departure delay of 3.3 minutes relative to competing carriers that did not.

Fourth, passenger rights lead to stronger delay reductions on routes where competition is low. Theory shows that the relationship between competition and quality is ambiguous, and the empirical evidence is consistent with this. Mazzeo (2003) shows that delays fall when a route moves from a monopoly carrier to duopoly, while Ater and Orlov (2015) show increased competition due to Internet penetration worsens on-time performance. Similarly, Prince and Simon (2014) find that (actual or threatened) entry by Southwest, a low-cost airline, worsens incumbent on-time performance.[4] In our model, these route-level delay effects are captured by the route-time fixed effect, allowing us to focus on the interaction between the effect of the regulation and route competition. Our results show that EC261 leads to stronger delay reduction when market concentration, as measured by the Herfindahl-Hirschman index, is high.

The paper continues by introducing the EU Air Passenger Rights regulation the following section. Section 2 then discusses our identification strategy, addressing both specification and the sources of variation we exploit; this is followed by the data description. Section 4 presents the key results on delay impact, followed by a discussion of the underlying mechanisms in section 5. Lastly, section 6 concludes.

1. EU Air Passenger Rights Regulation

Air passenger rights in the European Union are laid down in Regulation 261/2004 (henceforth EC261). With the aim of "ensuring a high level of protection for passengers", the regulation grants passengers certain rights against the carrier operating the flight,[5] should certain *liability events*[6] arise. The regulation is mandatory, so passengers and airlines cannot agree through conditions of carriage to limit or waive rights created by the regulation. Of central interest in this paper are passenger rights in case of flight delay. The regulation is concerned with "long delays" in arrival *at the final destination* exceeding three hours. Thus, missed connecting flights qualify as a reason for long delay. In case of a long delay, passengers have a right to care and assistance. This includes free phone calls, meal vouchers and – in case of overnight stays – hotel accommodation, which must be fully covered by the operating carrier.

---

[4] In Europe, LCC entry may improve on-time performance (Bubalo and Gaggero, 2015).

[5] The *operating carrier* is always liable under the regulation, irrespective if the ticket was sold through another carrier.

[6] Denied boarding, flight cancellation or long delay

Such care must always be granted, irrespective of who is at fault for the delay. Additionally, passengers receive the right to claim substantial cash compensation for lost time, which is due unless the airline can prove the delay was caused by "exceptional circumstances".[7] This compensation ranges from EUR 250 for a three-hour delay on a short flight of less than 1500km to EUR 600 for a delay of at least four hours on a long-haul flight with distance exceeding 3500km (see appendix table 3 for details). Reflecting the motive of compensation, these cash payments are not limited by the ticket price; thus, the airline may well need to refund more than 100% of the ticket price in case of long delay. Figure 1 summarizes these remedies under the EC261 regulation.

Figure 1: EC261 Passenger Rights: The Case of Long Delay

EU Passenger Rights Apply

Right to care (including meals and accommodation)
Re-routing (to reduce delay)
Cash compensation (from €250 to €600 for delays over three hours at final destination)

No Coverage

Source: Compiled by authors based on Bobek and Prassl (2016) and European Union (2016)

Coverage of the regulation is broad but not universal. All flights departing from an airport located in the European Union[8] fall under the scope of EC261. The situation is more interesting for routes headed to an EU-airport but originating outside the EU. On such routes, flights operated by a carrier from an EU member state must grant EC261 passenger rights. But flights operated by non-EU carriers are under no such obligation. And in practice, non-EU carriers also do not voluntarily grant equivalent passenger rights on these routes. This quirk in coverage, summarised in Figure 1, will be fundamental for identification, as described in section 2.

EC261 was significantly shaped over time by case law and implemented gradually against the continued opposition of airlines. This is particularly true for delay compensation. The original text of the regulation explicitly rules out cash compensation for delay, reserving it for the case of flight cancellation. However, in the controversial landmark *Sturgeon case*[9] (Garben, 2013), the European Court of Justice in 2009 determined that a long delay has an effect equivalent to a cancellation, and accordingly compensation should be paid. This ruling thus drastically broadened the scope of EC261 compared to earlier practice. However, public awareness of passenger rights was initially low, leading few passengers to make the claims they were entitled to (European Commission, 2014). It also met fierce resistance from airlines, who initially refused to apply the ruling to those few passengers that did seek

---

[7] Perhaps the most well known case which brought the EC261 regulation into the spotlight was the volcano ash clouds following the Eyjafjallajökull eruptions in spring 2010. 107,000 flights were canceled during an 8-day period following the eruption, accounting for 48% of total air traffic in EU and roughly 10 million passengers. The ash-cloud is treated as an extraordinary circumstance, so airlines were exempt from disbursing cash compensation. The airlines, however, were obliged to provide care, including accommodation and food, for the affected passengers.

[8] Additionally, some non-EU countries also apply the regulation. Examples include Switzerland and Norway. When we talk of "EU countries", we mean to include also non-EU countries which apply EC261.

[9] Christopher Sturgeon, Gabriel Sturgeon and Alana Sturgeon v Condor Flugdienst GmbH (C-402/07)

compensation. Over time, so–called "claims agencies" proliferated. These agencies charge a contingency fee to distressed passengers and credibly threaten to sue airlines in case of non-compliance with the *Sturgeon* ruling. Over time, these developments made the initial opposition of airlines untenable, and rising public awareness may have caused an increase in claims.[10] Due to this gradual implementation, before/after analyses are not feasible to assess the impact of EC261.

European Passenger rights in case of delay are exceptionally strong compared to other major aviation markets (see ICAO (2013) for a survey) or other modes of transport. In the US, the Department of Transportation relies on the market, aided by its delay transparency program, to deal with flight delay.[11] Its *Consumer Guide to Air Travel* informs passengers that "there are no federal requirements" for assistance or care in case of delays; passengers are advised to take note of each airline's "own policies" and engage in "defensive planning". Notably, Israel and Saudi Arabia, Indonesia and New Zealand introduced passenger rights legislation including assistance and compensation in case of long delays; however, their specific regulations are beyond the scope of the present paper. From a global perspective, the potential of airline passenger rights is still largely untapped.

Airlines sometimes implement voluntary approaches to ease the burden on passengers affected by extreme delays. In the US, some airlines offer discounted hotel accommodation in case of delay ("distressed passenger rate"). Others encourage consumers to purchase third-party travel insurance, which may provide assistance in case of delay. Finally, some airlines offer delay insurance as an ancillary purchase, perhaps to signal their reliability. For example, one European low-cost carrier offers an "On-time Guarantee" at a charge of EUR 10; in case of a delay exceeding one hour, the "guarantee" pays EUR 100 in flight vouchers to the consumer. Clearly, the protection offered here is more limited than under EC261; whether this reflects a market failure or simply low consumer demand for insurance is a separate issue we do not seek to tackle here.

2. Identifying the EC261 Effect

Our cross-sectional unit is a flight number, indexed *f*, and time unit *t* is a calendar day. For each flight number, we observe the $Route_f$ on which it is operated, and whether this route starts in a non-EU airport and terminates in an EU airport (denoted by $EU\text{-}bound_f$). We also have the $Airline_f$ which is operating the flight as well as whether this airline is "Community Carrier" under EC261 (denoted by $EUCarrier_f$), and whether the flight departs from an airline hub, denoted $FromHub_f$.

Then our primary estimating equation follows a fixed effects strategy and is given by

$$y_{ft} = \beta EUCarrier_f \times EU - bound_f + Route_{ft} + Airline_{ft} + \gamma FromHub_f + \varepsilon_{ft}$$

where y_{ft} is our dependent variable of interest, primarily gate departure delay. Our main goal is to estimate β, the impact of being covered by the EC261 which is estimated using within-route variations in coverage on EU-bound flights, as discussed above. We allow for airline fixed effects to capture innate differences between them, which is standard. Moreover, we allow for a *route-time* fixed effect, which controls for transient, route-specific factors such as airspace congestion or local conditions at either arrival or departure airport; these fixed effects also absorb the effect of EC261 on routes departing from EU, where there is no variation in coverage.

---

[10] Airlines do not publish information on claim rates. The European Commission estimates that only approximately 10% of eligible passengers request compensation.

[11] However, the US Civil Aviation Authority created a right to compensation in case of denied boarding in 2011, which follows the EC261 model for this specific liability event.

Inclusion of route-time fixed effects is a particular luxury of our setting because our variation is *within* the route-time dimension, while other airline delay studies typically explore market or policy changes collinear with route-time. Controlling for route-time fixed effects is especially crucial in the European setting and the European slot control system.[12] Due to route-time fixed effects, standard controls such as weather, airport concentration, congestion indices or demographic variables, are not required. Instead, we have to control for possible confounding factors that are correlated with $\beta EUCarrier_f \times EU - bound_f$ after removing airline and route-day group means.

Based on the literature, the need to control for airline-hub status is clear. Mayer and Sinai (2003) conduct a study of determinants of excess travel time for US domestic flights; after controlling for airport-level covariates (airport hub size and airport concentration), which in our design would be absorbed by route-time FEs, they find that airline hubbing is a significant determinant of excess travel time.[13] Furthermore, Rupp (2009) conducts a study with similar controls but using departure delay as a dependent variable, which is most closely related to our dependent variable. His results indicate a statistically significant increase in departure delay from airline hubs of over two minutes; hub status at destination has no impact on departure delay.[14]

Our baseline control strategy is to include an airline-hub indicator. This takes the value one if a carrier is operating connecting flights from a given airport. In other words, connections operated by code-share are not considered hubbing; if we were to broaden the definition in this direction, the airline-hub dummy would nearly always take the value of one. This specification is consistent with Mayer and Sinai (2003), who find the hub effect to be statistically indistinguishable between medium and large airline hubs.[15]

2.1 Sources of Variation

We have considerable variation in EC261 coverage, with around half of inbound EU flights not covered, but there is some collinearity of the treatment with airline hub status. This arises from the legacy airline model, where "flag carriers" operate hubs in their home countries, and start international flights from these hubs. Hence, on a route originating outside the EU, legacy EU carriers never depart from a hub, while legacy foreign carriers always do. Hence our variation in coverage, , is colinear with a combination of airline and route fixed effects as well as the hub indicator *among legacy carriers*. This can cause a loss of precision, as it becomes harder for the model to disentangle EC261 and the hub effect.

It is possible to rely on the limited within-variation in hubbing structure created by carriers operating purely point-to-point (P2P) models to disentangle these two effects. These carriers do not operate connecting flights, and hence fail to satisfy the classical definition of a hub. This breaks the multicollinearity and makes it possible to estimate the model. However, this source of variation is

---

[12] To reduce environmental pollution and increase safety, European air traffic control (ATC) works according to a slot control system. Under this system, ATC assigns a Calculated Time of Take Off (CTOT) taking into account expected conditions at the arrival airport based upon the predicted time of arrival. The objective of this system is to reduce the time planes spend flying in a "holding pattern" over the arrival airport while waiting for a landing slot (see Eurocontrol (2016)) An important consequence is that a departure in, say, Miami, may be delayed due to expected congestion in Heathrow 9 hours later. Since Heathrow is one of the most congested airports in Europe, the ability to include route-time fixed effects is particularly valuable for our present study.

[13] Determinants of delay are similar in Europe but coefficients differ, according to Santos and Robin (2010), who use a similar study design.

[14] See table 6 in Rupp (2009)

[15] Due to the focus of our sample on most traffic-intensive routes, we do not have small hubs in the dataset.

limited – the bulk of flights on long-haul routes are accounted for by legacy carriers – and the particular airlines may not be typical.[16] Hence it is not satisfactory to rely on this variation alone.

Secondly, we include additional routes *not* subject to EC261 to get more data which can tie down the hub effect. On US domestic routes, where flight data are easily available from the Department of Transportation, the EC261 treatment is always zero but we have strong variation in hub status. Thus, we extend our sample with domestic flights of US carriers among the US airports. The selection criterion is that both the carrier and each airport should already be included in the sample. This creates separate variation which ties down the hub effect. For robustness, we also allow the airline-hub effect to vary by airline.[17]

EC261 creates small variations in coverage across domestic EU markets, and large variation in coverage within markets that involve a non–EU airport. For EU–domestic flights, rights to care always apply, although the size of the compensation for lost flights increases discontinuously when the distance exceeds 1500km. Exploiting this variation is difficult, as it would be collinear with route-fixed effects. For this reason, we focus on within-route variation on international routes with one leg outside the EU.

3. Data

We define each airport pair as a transportation *market*, which consists of two directional *routes*.

3.1 Flight Data: Extra-EU Routes

We have collected scheduled and actual flight times of all scheduled commercial flights on the top 15 most traffic intensive extra-EU markets over an 8-month sample period. The choice is driven by a trade-off between statistical power and cost, as flight data must be purchased commercially.

Based on *Eurostat* data, we obtain number of passengers carried by transportation market in 2016.[18] The leading international routes are entirely "category 3" flights (i.e. extra-EU over 3500km), with one exception.[19] To make sure that the EC261 is uniform throughout the sample, we limit our attention to category 3 markets only. The full map of extra-EU routes considered in the sample is shown in figure 2.

We obtain scheduled and actual flight data from *FlightAware*, a commercial vendor. The sample period, which is determined by the time of data collection only, runs from 4th November 2016 to 6th July 2017. Flight schedule information is based on airline data available to the vendor. Actual flight data are collected by the vendor from two sources. Actual gate departure and gate arrival times are based on airline-reported times. Take-off and landing times are based on satellite position data the vendor obtained from the ADS-B system, a radio transponder installed on all commercial aircrafts.[20]

---

[16] In our baseline sample, point-to-point models appear in conjunction with new carriers (i.e. who were not previously legacy carriers) and fifth-freedom flights, as discussed below.

[17] We thank Ricard Gil for suggesting this.

[18] Database: avia_par

[19] The exception is Düsseldorf-Antalya, which is top 15 in terms of passenger volume but has a great circle distance below 2500km (i.e. a category 2 flight). This route has been replaced in our data set with the 16th most busy extra-EU market; London Heathrow – Newark.

[20] Collection of individual flight data is crowd-sourced to thousands of radio enthusiasts around the world. Data collectors equipped with simple, often home-made radio receivers can track signal from all aircrafts up to 150 miles away. The signal is then sent to a flight data provider, processed, and published on-line.

Figure 2: Map of Extra-EU Routes
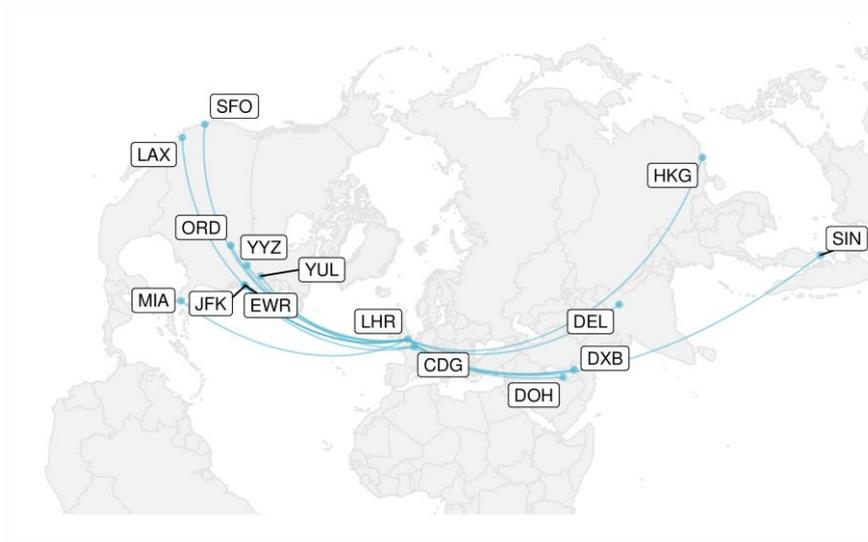

Notes: For airport codes, see table **4**

Source: Authors.

We then apply a data cleaning procedure following Forbes et al. (2015) on this data set: first, we remove all flights with incomplete flight data[21] and those which did not reach their destination (due to diversion or cancellation). Second, we drop all flights where the actual gate departure precedes the scheduled gate departure by more than 15 minutes or which arrive more than 60 minutes ahead of schedule; these observations likely represented corrupted data (e.g. due to rescheduling). Finally, we limit the sample to carriers for which data on flights on more than one route are available. This leaves us a total of 48426 flights.

We supplement the flight data with a list of hub airports for each carrier in the sample, according to the hub definition outlined in the previous section (see appendix table 4 for details). Flight volume and the number of carriers active are highly variable depending on the transportation market. Figure 2 and appendix tables 4 and 5 show the details. Some markets, typically with high passenger volume, experienced entry, including by the EU based point-to-point carrier Virgin Atlantic. The former is crucial for identifying the hub effect. As shown in appendix table 6, those flights cover for 20% of the EU-outbound flights operated by an EU-carrier. An additional source of variation comes from so-called "fifth freedom" flights, i.e. flights between foreign countries as a part of services connecting the airline's own country. Air New Zealand, for example, operates a connection from Los Angeles to Auckland with a stopover in London Heathrow.[22] The "fifth freedom" flights make up 2% of the EU-bound flights operated by a non-EU carrier that do not depart from a hub.

Furthermore, the descriptive tables show considerable variation in competition. US markets, for example, have at least three carriers – two US, one European – while many Asian and Canadian markets still have only two carriers. This variation in competition will be useful later on to assess how regulation interacts with the intensity of market competition.

---

[21] A complete flight record contains information on the following key flight phases: scheduled gate departure, actual gate departure, take-off, landing, actual gate arrival and scheduled gate arrival time.

[22] Importantly, these stopovers do not serve only refueling, as airlines operating the "fifth freedom" flights are allowed to sell tickets for each leg separately.

3.2 Flight Data: US Domestic Routes

To create more within-airline hub variation to improve our control strategy for the hub effect discussed above, we obtain flight-level data for US domestic flights from the US Department of Transportation for the entire sample period. Specifically, we include data on all flights operated by all (three) US-based carriers between all (six) US airports in our main sample; 88731 flights in total. This dataset contains the same variables as our FlightAware data set for extra-EU flights. We apply also the same data cleaning procedure as mentioned above. The US legacy carriers typically operate from multiple hubs; nevertheless, 14% of the US domestic flights in our sample were not operated from carrier's hub.

On average, flight quality measures are very similar in both samples. 74.4% of the extra-EU long-haul flights arrive within 15 minutes of the scheduled arrival. The score for the US domestic flights is only 1.3% lower. The US domestic flights, however, have longer average departure (14.9 min vs 9.3 min) and arrival delays (7.4 min vs 3.7 min).

We compute our baseline estimates combining the two data sets, which contain 137157 observations in total.

4. Results: Delay Impact of EC261

We find an economically important and statistically significant effect of EC261 regulation on both departure and arrival delay, as well as on-time performance. Estimation results are presented in table 1, where column (1) reports results for departure delay. Our model attributes a delay reduction of 4.92 minutes on average to the EC261 regulation, after controlling for airline-hub status, route-time fixed effects and airline fixed effects. This estimate is certainly large compared to an average departure delay of 10 minutes on international routes, and economically important. Statistically, we can very robustly reject the hypothesis of no effect (at the 1% level). However, the standard error is relatively large at 1.11 minutes, so there is some uncertainty associated with the precise magnitude of the effect. The same holds for arrival delay, where the estimated EC261 impact is 3.90 minutes of delay reduction. As column (3) shows, EC261 is associated with a 5% improvement in "on-time performance" (i.e. whether arrival delay is below 15 minutes). Finally, for delays exceeding three hours, the coefficient estimate is low with high standard error; this imprecision is not surprising, because only 0.5% of extra-EU flights in our sample arrive that late.

These results suggest that EC261 has an important impact on flight quality through improving mean performance, rather than reducing the likelihood of extremely poor performance. At first pass this appears surprising because the liability events under the regulation focus on long delays. However, it is important to note that delay *at final destination* is what matters for the regulation; carriers operating connecting flights have a strong incentive to make sure their passengers don't miss connections. This suggests one source of heterogeneity in the EC261 effect, since carriers offering point-to-point service only do not face this incentive.

Table 1: Delay Impact of EC261

Dependent Variable	Departure Delay (minutes)	Arrival Delay (minutes)	Arrival On time	Arrival Delay >180min
	(1)	(2)	(3)	(4)
EU-bound$_f$ × EU Carrier$_f$	-4.92	-3.9	0.054	-0.004
	(1.11)	(1.20)	(0.014)	(0.003)
From Hub$_f$	3.6	3.31	-0.046	-0.002
	(0.53)	(0.58)	(0.006)	(0.002)
Num. obs.	137157	137157	137157	137157
R^2 (full model)	0.25	0.31	0.28	0.31

Notes: All regressions include airline and route-day fixed effects. Standard errors are clustered at the route-day level. Arrival on time and Arrival delay >180 are binary variables that takes value one if a flight arrives within 15 minutes of the scheduled arrival time and over 180 minutes after the scheduled arrival time respectively, and zero otherwise. *Source*: Authors.

The baseline results are robust to changes in the estimation sample. Our baseline results are based on the full sample, which complements extra-EU flights with US domestic flights. In appendix table 7, we estimate the same departure delay specification, but splitting the sample according to the sources of variation identified in the previous section. The point estimates in a subsample restricted to the extra-EU flights only show a smaller EC261 effect, and a larger hub effect. However, precision suffers due to the multicollinearity issues discussed above. Restricting the sample even further to the EU-US routes only does not significantly affect the point estimates. Excluding point-to-point carriers from the main sample leads to a much larger EC261 effect on delay, consistent with connecting passengers being an important part of the EC261 incentives. Throughout all specifications, the hypothesis of differences of coefficients between the subsamples can be statistically rejected at standard significance levels.

These results are also robust to changes in specification. One possible generalization is to allow the hub effect to vary by airline, e.g. because connecting flights are operated differently. Columns (1-2) of appendix table 9 contains results for this specification. Given the nature of our dataset, we have within airline-hub variation for EU-US transportation markets; thus, the other routes do not contribute to the estimate of EC261 impact under this specification. Hence, the results of this specification should be compared to column 5 of table 2; the differences in coefficients are small in magnitude and not statistically significant. As a further robustness test, we replace the route-day fixed effect with a route-time fixed effect in columns (3-4) of the table. For each route, we split flights into time windows with a duration not exceeding 60 minutes according to an optimal matching algorithm; each time window must contain at least one EU carrier and one non-EU carrier. Hence, the route-time fixed effect can capture even very short term systemic delay causes. Adopting this specification considerably increases, which is not surprising, and does not significantly affect the estimated EC261 coefficients. However, due to the invariably smaller sample size, precision suffers. Hence, in the following regressions, we return to the baseline specification with a hub dummy variable and a route-day fixed effect.

Delay reductions of EC261 cannot be explained by "gaming", such as airlines strategically increasing scheduled flight times or affecting other flight phases (see figure 3 for details) to reduce measured delay. On the one hand, the fact that EC261 has a strong effect on departure delay already rules out schedule padding as an alternative explanation. Indeed, as shown in the Appendix table 8, the airlines affected by the EC261 regulation actually operate on tighter schedules than their unregulated competitors. EU legacy carriers schedule their flights back to Europe to be 4.5 minutes shorter than their foreign legacy competitors. As the remaining columns of the table show, EU carriers also have actually shorter in-air times and shorter taxi-in times. This is likely due to a combination of two factors: on the one hand, fleet

effects – some planes fly faster than others – may explain the shorter in-air time.[23] Secondly, more favourable positioning of terminals (relative to runways) reduces taxi-in times; the pattern we observe could be explained by airlines having more favourable locations in their home airports as compared to foreign airlines operating from the same airport.

These results provide strong evidence that EC261 leads to a meaningful improvement in airline service quality. This improvement was driven by a reduction in mean delay both at the gate departure and gate arrival level, rather than a reduction in the probability of severe delay only. Accordingly, there is evidence for improved on-time performance, defined as 15 minutes arrival delay or less and limited evidence of a reduction in extreme delays (defined as delays exceeding three hours). Moreover, there is some evidence that the effect is heterogeneous across carriers: excluding point-to-point carriers from the sample leads to an even stronger EC261 effect. In the analysis that follows, we explore more closely how the EC261 impact interacts with airline and transportation market characteristics.

5. Discussion: What drives EC261 Impact?

To better understand the driver of EC261 impact, this section investigates heterogeneity according to airline and transportation market characteristics. Our discussion is organized around the results shown in table 2.

Due to the regulatory focus on delay "at final destination", EC261 affects legacy airlines more strongly than point-to-point carriers. As column (1) of table 2 shows, this is reflected in a weaker EC261 delay reduction impact on point-to-point carriers as compared to legacy ones. By the point estimates, the delay reduction is around 25% smaller for point-to-point carriers. Although the estimate is not statistically significant, this is not entirely surprising given the relatively small market share of point-to-point in the transportation markets we consider.

Routes with weaker competition have a stronger EC261 impact. Prior research has found mixed results on competition and airline service quality; e.g. Mazzeo (2003) found that competition increases service quality, while Ater and Orlov (2015) found that competition actually increases delays. How regulation interacts with market competition is similarly an open question. One possible mechanism is that under low competition, airlines exert little effort to reduce delays. In this case, the marginal cost of delay reduction is likely to be low, and the regulation can have a significant effect. We test this hypothesis by interacting the EC261 effect with the Herfindahl-Hirschman index, bearing in mind the limitations of our sample which contains only 15 markets affected by EC261. We first add a linear interaction between the route Herfindahl-Hirschman index and the EC261 effect. The results are presented in column (2) of table 2. The estimate favors a linear relationship between the route Herfindahl-Hirschman index and EC261 effect. Given the distribution of HHI in the sample, the effect ranges from 2.53 minutes of delay reduction on the most competitive routes to 7.78 minutes on the least competitive routes. As a robustness test, we interact the EC261 with an indicator if the route HHI exceeds the median HHI in column (3). This yields essentially the same results. Thus, there is evidence of a negative interaction between market competitiveness and the impact of EC261.

---

[23] Conditional on aircraft type, the freedom to choose cruise speed at will is limited. On the one hand, slot control system at congested airports requires airlines to assess the flight time before departure. On the other hand, fuel economy and technological considerations play a role. For a typical airliner, the range between the cruising and maximum speed is rather narrow, making it difficult for airlines to reduce flight delay after take-off. Airbus A340-642 flying between London and New York (5555km) a speed increase from the aircraft's cruising speed (0.82M or 871 km/h) to the maximum speed allowed by the aircraft producer (0.86M or 914 km/h) decreases the flight time only by 17min (or 4%). This reduction comes, however, at quite a substantial cost. Fuel consumption increases by more than 20% or 10 tonnes of jet fuel, which would cost more than $20,000 extra (simulation performed using freeware Aircraft Emissions and Performance software Piano-X (available at http://www.piano.aero/)).

Enforcement of EC261 is national, although the letter of the regulation applies uniformly across the EU. In the legal literature, the role of national differences in implementation of regulations is frequently debated (e.g. Bobek and Prassl (2016)). Our sample only contains two EU member states, so our power to reject equal effects across EU member states is low. We could expect to reject the hypothesis only if the true heterogeneity is very large. This does not appear to be the case: column (4) shows no evidence of heterogeneity in enforcement, at least between the UK and France.

Lastly, we consider heterogeneity by non-EU region. This is potentially important, because the population of non-EU carriers is significantly different across regions. Several Asian carriers have successfully pursued a strategy of product differentiation offering higher service quality than European and North American legacy carriers. Partly, this is to make the carriers more attractive to connecting passengers, an especially important factor for the Gulf airlines. Therefore, these airlines may be exerting high effort to avoid delays, at a similar level as regulated European airlines, even in the absence of EC261 coverage. To test this hypothesis, column (5) interacts the EC261 with a dummy indicating if the non-EU region is in North America. This seems to be a very powerful discriminator: the impact of EC261 on non-North American routes becomes small and statistically insignificant, while the impact on North American markets becomes even larger and statistically more powerful.

6. Conclusion

Consumer rights legislation has rapidly proliferated in the European Union, and covers many sectors of the economy. Besides passenger rights, examples include a statutory minimum warranty period for consumer durables, a consumer's right to repay a credit early or a "cooling off period" to change one's mind about an online purchase. These regulations increasingly constrain the freedom of contracts between firms and consumers. But little is known about the impact of these laws, whether directly on consumers with a grievance or indirectly through changes in industry service quality. This paper begins

to fill the void by studying the impact of a specific form of consumer rights regulation, air passenger rights, on service quality within the affected industry.

We exploit the partial application of regulation EC261 on routes bound for EU but originating outside the bloc. On these routes, carriers from the EU are covered by the regulation, while foreign carriers are not; in contrast, on routes originating in the EU, all carriers are covered. This variation in coverage makes a difference-in-differences strategy feasible.

We find robust evidence that the regulation is effective in improving airline punctuality. Our baseline regression focuses on gate departure delay, because this measure – unlike arrival delay – is not affected by scheduled flight time, which is chosen by the airline. This model shows a delay reduction of nearly five minutes due to the regulation; for arrival delay, we obtain qualitatively the same result, but the point estimate is smaller (3.9 minutes). The regulation also leads to a 5% improvement in "on-time" performance. In further analysis, we find the regulation to have a weaker effect on point-to-point carriers, and a stronger effect on routes with weak competition.
